COURSE DETAILS:

Course Coordinator: Dr. A.O. Agbon  
Email: oseremehis@yahoo.co.uk  
Office Location: Room D205, COLERM  
Other Lecturers: Dr. W.O. Abdul

COURSE CONTENT:

General surveying, site selection; fresh water and brackish water pond construction. Design and construction of dykes, sluice gates, drainage facilities, tanks, ponds, pens, cages, rafts etc. design and construction of Kiln drying chambers, machines.

COURSE REQUIREMENTS:

This is a compulsory course for all students in Department of Aquaculture & Fisheries Management. In view of this, students are expected to participate in all the course activities and have minimum of 75% attendance to be eligible to write the final examination.

READING LIST:

FOA Training Series: simple methods of Aquaculture pond construction

LECTURE NOTES

AQUACULTURE ENGINEERING POND CONSTRUCTION

A pond is a water enclosure or a confined body of water where fish are raised or reared under a manageable controlled condition. Pond could either be earthen or concrete. Nowadays fish are raised in plastics, fiberstars and wooden rafts which are either locally fabricated or imported from developed countries. But here, in this course, emphases are laid only on earthen and concrete pond constructions.

TYPE OF PONDS (Earthen)

There are two major types, namely:
(i). Excavated pond  
(ii). Embankment/ pond

Sometimes, depending on the terrain or topography of the site, there is what we called excavated- levee pond, barrage pond and contour pond.
Site selection for fish pond construction:
The failure or success of fish farm enterprise depends on the selection of a good site. The layout and the management of fish farm will largely be influenced by the kind of site selected. The site has the following influences:
(i). strongly affects the cost of construction
(ii). amount of fish that can be produced
(iii). ease of pond management
(iv). the economics of the enterprise
During the lecture the distinctions shall be made clear to students diagrammatically

Decisions prior to site selection:
a) Do I have a clear ideal of the type of fish farm I want to construct
b) Of what production level is my target?
c) What is the system of culture to be adopted?
d) Which fish species should be produced?
e) Is it necessary to produce fingerlings for the farm?
f) At what stage of fish should you start selling?
Answers to these questions will assist greatly during site selection exercise
Define kind of site needed
Can you find this site?
Reconnaissance Survey
water - soil - topography
Ca you change the site
that is needed?
Can you change what you want to do?
Look for alternative solutions
Decides what you want to do
Figure 1: Site selection decision-making cycle
Factors to consider when selecting site for fish farm construction
a) Water — quantity, quality, source, activities around it
b) Nature of soil — texture, permeability, retention ability, etc
c) Topography of the land
d) Environmental consideration
e) Accessibility
f) Vegetations density/cover
g) Expertise
Other important factors include:
h) Proximity and size of market
i) Poaching
j) Availability of farm inputs
Detailed planning for fish farm construction
Once the site has been selected, then initiation of planning begins. There are two main related components of planning in construction. These include:
a) Organizational planning —decides where, how and which order the farm is to be built.
b) Physical planning — decides on layouts, detailed design and earthwork.
SITE SELECTION
Students are to be given practical exposure with training manual on the necessity of these aforementioned factors
RECONNAISSANCE SURVEY
Water - soil - topography No
Does site meet requirement? Return to site selection process
Yes
DETAILED SURVEY Yes
Soil - Topography
Try out sketches of the layout
Do they meet your needs? Is there a problem with?
Yes the site?
Prepare detailed draft layout
Earthworks and water levels satisfactory?
No
ALL ok?
Yes
Prepare final detailed Design
Prepare final evaluation of the site
Figure 2: Flow - chart on matching the fish farm and its layout to the selected site
Things include:
1. Time of construction
2. who will construct the fish farm?
3. How will the construction be carried -out?
These when critically considered, may lead to further activities such as
a) Some more detailed plan and drawings
b) A series of specifications for the contractor
c) A detailed schedule of activities will be drawn.

Steps involved in earthen ponds construction
The following steps are required:
• Clearing of proposed site
• Setting-out which involves site clearing
• Mark-out the areas inlet and outlet
• Topsoil removal and storage
• Construction of embankment
• Construction of inlet drainage pipes / water control structures
• Construction of screen at both inlet and outlet.
Figure 2 is to be used in ensuring proper and appropriate appraisal of the work to be done.
Assignment: students are expected to visit any chosen location at COLERM field and carry-out fish farm site selection exercise and prepare a report

Steps involved in block tanks for fish farming
• Clearing of proposed site
• Settings-out which involves pegging and lining with the rope
• Topsoil stripping to form strong basement
• Surface blinding with concrete mixture (sharp sand, cement , and gravel/ granite at ratio 3:1:6)
• Block laying and stuffing of holes with concrete mixture
• Placement of water inlet and outlet pipes
• Plastering of tanks

**Calculating dike and excavation volumes**

Width of the dike base

Base width = crest width + (CH x SD) + (CH x SW)

Where CH (in m) = construction height
SD = slope ratio of dry side
SW = slope ratio of wet side

While estimating this, use the constructing height as well as the settlement

**EXERCISE:**

A 0.04ha pond has to be built in clayey soil with dikes 1.50m high and 1m wide at the top. If SD = 1.5:1 and SW = 2:1. Calculate the base width of the dike (Hint: settlement allowance of expanded clay volume is 20%).

**Solution:**

Design height = (100% – 20%) = 80% of constructing height

Construction height = 1.50m/0.80 = 1.88m

Dike base width = 1m + (1.88m x 1.5) + (1.88m x 2) = 7.55m

CH = DH ÷ [(100 - SA) ÷ 100]

Calculating the cross-section of a dike on horizontal ground

For the above 0.04-ha pond to be built in clayey soil, calculate the size of the cross-section of the dike as:

- area 1 = 1 m x 1.88 m = 1.88 m²;
- area 2 = (1.5 x 1.88 m) x (1.88 m ÷ 2) = 2.6508 m²;
- area 3 = (2 x 1.88 m) x (1.88 m ÷ 2) = 3.5344 m²;
- cross-section = 1.88 m² + 2.6508 m² + 3.5344 m² = 8.0652 m².

Calculating the cross-section of a dike on sloping ground

The cross-section of a dike on sloping ground can be calculated most easily using a scale drawing.

(a) Draw a horizontal line from D, meeting AE at E'.
(b) Draw a horizontal line from C, meeting BF at F'.
(c) Draw a vertical line PO down the centre line of the dike.
(d) Cross-section = ADE + AEFB + BFC = 0.5(AE x DE') + (AB x PO) + 0.5(BF x F'C).

Note: Design height, DH, is the height dike should have after settling down to safely provide the necessary water depth in the pond = Water depth + Free board.

Construction height, CH, is the height the dike should have when newly built and before any settlement takes place. =design height + settlement height

**Calculating the cross-section of a dike on sloping ground using a scale drawing**

**Calculating the cross-section of a dike on irregular ground using a scale drawing**

**Calculating the cross-section of a dike on irregular ground using squared paper**

1 cm = 0.5 m

1 square of 0.5 m x 0.5 m = 0.25 m²

15.2 squares x 0.25 m² = 3.8 m².

**Calculating the volume of dikes on horizontal and regular ground**

To estimate how much soil will be needed for the construction of a dike, you need to know its
volume. The calculation method depends on the site topography and on the type of pond to be built. If the topography of the construction site is reasonably flat (less than 0.30 m difference in average site levels) and regular, you can calculate the volume of the dike (in m³) by multiplying the crosssection of the dike (in m² and halfway along the dike for an average area) by its length measured along the centre line (in m).

**EXAMPLE**

Using the figures from the example above, the cross-section of the dike equals 8.0652 m². If the length of the dike to be built is 20 m x 4 = 80 m, its volume is 8.0652 m² x 80 m = 653.216 m³.

**Calculating the volume of dikes on sloping or irregular ground**

If the topography of the site is more steeply sloping or more irregular, you cannot calculate the volume of the pond dikes just by using one cross-section. There are several possible methods, depending on the type of ground and the accuracy you require.

With a first group of methods you can calculate the dike volumes by using averages of the dike crosssections or you could use the average of the cross-sections at the corners of the dike.

**Exampke**

A 400-m² (20 x 20 m) pond is to be constructed with wall heights of 0.5 m at corner A, 0.3 m at corner B, 1.1 m at corner C and 1.5 m at corner D. Crest width is 1 m and side slope 2:1 on both sides. The cross-section areas at each corner are:

A: (1 m x 0.5 m) + 2 x (0.5 m x 0.5 m x 1 m) = 1.5 m²,
B: (1 m x 0.3 m) + 2 x (0.5 m x 0.3 m x 0.6 m) = 0.48 m²,
C: (1 m x 1.1 m) + 2 x (0.5 m x 1.1 m x 2.2 m) = 3.52 m²,
D: (1 m x 1.5 m) + 2 x (0.5 m x 1.5 m x 3 m) = 6.0 m².

Average area for wall AB = (1.5 m² + 0.48 m²) ÷ 2 = 0.99 m² and volume for wall AB = 0.99 m² x 20 m = 19.8 m³.

Similarly:

• for BC, average area = 2 m² and volume = 40 m³;
• for CD, average area = 4.76 m² and volume = 95.2 m³;
• for DA, average area = 3.75 m² and volume = 75 m³.

Consequently, total volume of dikes = 19.8 m³ + 40 m³ + 95.2 m³ + 75 m³ = 230 m³.

**Average of areas at corners of dike**

For a more accurate measurement of dike volume on rough ground, you should apply the following formula, known as Simpson’s rule, where: \( V = \left( \frac{d}{3} \right) \times [A_1 + A_n + 4(A_2 + A_4 + ... A_{n-1}) + 2(A_3 + A_5 + ... A_{n-3})] \).

Proceed as follows:

(a) Divide the length of the dike into an odd number \( n \) of cross-sections at equal intervals of \( d \) metres.

(b) Calculate the area \( A \) of each cross-section as explained earlier.

(c) Introduce these values into the above formula.

The dike is 60 m long.

(a) At intervals \( d = 10 \) m, identify seven crosssections \( A_1 \ldots A_7 \) and calculate their respective areas to obtain \( A_1 = 10 \) m²; \( A_2 = 16 \) m²; \( A_3 = 18 \) m²; \( A_4 = 11 \) m²; \( A_5 = 8 \) m²; \( A_6 = 10 \) m²; \( A_7 = 12 \) m².

(b) Introduce these values into the Simpson’s rule formula:

\[ V = \left( \frac{10}{3} \right) \times [10 + 16 + 4(16 + 11 + 8 + 10) + 2(12 + 8)] = \]

740 m³.

**Calculating volumes of excavated material**
You will need to know excavation volumes for:

- topsoil;
- borrow pits, dug near an earth structure to provide the material for its construction;
- excavated ponds, to provide the pond volume required;
- other structures such as harvest pits, supply channels, etc.

You will normally have to remove the topsoil before you reach soil good for construction material. Levels should therefore be taken from the base of the topsoil layer. In most cases, the sides of the excavation should be sloped to prevent them from collapsing. In many cases (ponds, channels, etc.) these will be of specified gradients.

For reasonably flat, level surfaces, where excavated width is at least 30 times the depth, volume of excavation can be estimated as:
\[ V = \text{top area} \times \text{depth of excavation}. \]

Where the width is less than 30 times the depth, you should correct for side slopes as follows:
\[ V = \frac{\left[ \text{top area} + \text{bottom area} \right]}{2} \times \text{depth}. \]

**EXAMPLE**

A 400 m² (40 x 10 m) area is to be excavated, 1 m deep, with side slopes 2:1. As the width (10 m) is less than 30 times the depth (30 x 1 m), the first method is not accurate (estimated volume would be 400 m² x 1 m = 400 m³).

Use the second method, where
top area = 400 m² and base area = base length x base width.

Base length = 40 - (2 x slope x depth) = 40 - (2 x 2 x 1 m) = 36 m
Base width = 10 - (2 x slope x depth) = 10 - (2 x 2 x 1 m) = 6 m
Base area = 36 m x 6 m = 216 m²
Average area = (400 m² + 216 m²) ÷ 2 = 308 m²
Volume therefore = 308 m² x 1 m = 308 m³.

Above all, for precision, prismodal formula can be used to calculate the volume of soil excavated from pond area (excluding topsoil area):
\[ V = \frac{(A + 4B + C)}{6} \times D \]

Where
A = Top surface area
B = Mid-depth surface area
C = Bottom surface area
D = Average depth of excavation

**How to calculate the volume of water in the pond**

You have thus calculated the surface area of the pond and the average water depth of the pond. Now, using the figures you have found, you can calculate the volume of water in the pond by multiplying the surface in square metres (m²) by the average water depth in metres (m) to get

**Examples**

Surface
area
Average
water
depth
Water
volume
the volume of the pond in cubic metres (m³).
\[ \text{SURFACE AREA} \times \text{AVERAGE DEPTH} = \text{VOLUME} \]
(m²) (m) (m³)
235 x 1.0 = 235
450 x 1.2 = 540
2500 x 1.5 = 3750
Note: 1 cubic metre (m³) = 1000 litres (l). To
express water volume (in m³) in litres (l)
multiply by 1000. To express water volume (in
l) in cubic metres (m³) divide by 1000.
